That is how our court system runs. This paper examines the role of perpetual data generation in solving crimes and hints at the impact of open source on it. In 1975, the Canadian computer specialist, Paul Quayle, began to examine the use of computers for forensic purposes. After the end of 1982, he has developed a new model for crime investigation using computers. It provides a model of the computer record of a crime, and discusses the factors that lead to the generation of documents as evidence. Quayle's model consists of four parts, namely the method, the medium, the content and the context. These components interact with one another to produce an event that constitutes a record of the information generated by a crime. For Quayle, the structure of the model is important. To make a good record, the model suggests the use of all four parts. Each part should have an essential function. The methodology is the technical way of examining the evidence (e.g., the way it was generated). The most common methods are as follows: computer programs, which process raw data extractors, which process computer logs examiners, which examine data in place interpretation To process the data, a basic assumption is that the data is related to an event. For example, it is quite improbable that a computer record of a burglary would relate to the weather. The medium
