Â . Kontent Machine 3.26.18.100 Cracked & Working LThe brain of a person with Alzheimer's is

structurally modified to compensate for changes that have occurred in other parts of the body. Credit: NIAID Alzheimer's disease is an insidious, progressive disease that robs patients of their memories and, ultimately, their lives. It currently affects 25 million people worldwide, and no effective treatment is available. Scientists at the National Institute on Aging (NIA), part of the National Institutes of Health, have identified a new avenue toward the development of a treatment to slow the progression of the disease. They discovered that the brain changes that occur during Alzheimer's disease—changes that are similar to those that occur in other progressive diseases of aging such as Parkinson's disease and chronic traumatic encephalopathy (CTE)—are at least partially caused by a protein (JAK2) that is normally important in the repair of cells in the body and increases in the brain during disease progression. "We have exciting new findings about how this protein works in the brain to cause the known neuropathology associated with Alzheimer's disease," said Volker Haass, NIA's director, who is also the senior author of the study published Feb. 23 in *Neuron*. "Importantly, our data provides a potential explanation for why some people who have Alzheimer's disease develop additional symptoms and behavior changes such as depression and apathy, while others do not." Alzheimer's disease is a chronic illness that, if not diagnosed and treated early, progressively worsens over the course of a decade, reducing mental and physical capabilities. It is believed to be caused by abnormal protein clusters called senile plaques and neurofibrillary tangles, which accumulate in the brain and destroy communication and memory. In Alzheimer's disease, the loss of neurons and synapses that occur over time leads to widespread disconnection among neurons, and ultimately to dementia. CTE is a neurodegenerative disease characterized by brain trauma or repetitive head trauma. It is caused by an accumulation of a protein called Tau in the brain and can lead to memory loss, mood changes, aggression, and/or depression. Alzheimer's and CTE share many characteristics including the protein buildup, cell death, inflammation, and cognitive deficits. While scientists have known about this protein, called JAK2, since the 1990s, they didn't know its role in the body or the brain until recently. When researchers compared
