In order to create the conditions required to manage coral reefs, I think that the government must provide public resources, management training, support, and protection for coral reef organizations. In addition, attention should be paid to the health of local or long-distance coral reefs that are protected by marine protected areas (MPAs). In this situation, monitoring and conservation of coral reef ecosystems could be achieved. It is also important to recognize the need for and to ensure a sustainable social consensus for coral reef conservation and restoration (Shore 1987). Coral reefs are composed of soft corals that attach themselves to hard corals and other parts of the sea floor. These hard corals are formed of the skeletons of single-celled calcifying organisms, which are known as coral polyps. The integrity of coral reefs is maintained by competitive interactions between corals and their associates. The death of corals reduces competition, and it causes most of the biological and ecological changes that occur (Moore et al. 2003). Coral reefs are effective in sequestering vast amounts of carbon, since it is a carbonate producer that uses inorganic carbon, mainly carbon dioxide. Coral reefs also provide a habitat for fish, mollusks and other animals. They are also responsible for providing food, shelter and living space for numerous other organisms that include a variety of

sea birds and mammals. Corals from Okinawa to Australia and the Caribbean are the species of particular concern for reef restoration and thus proper identification is essential for their application and restoration. Hawaiian species are also included in the study because they have contributed significantly to studies of reef restoration and to the development of laboratory methods for such work. However, since species from Okinawa are primarily transported from Okinawa to Australia (and not vice versa), Okinawan species are not typical representatives of the genus *Acropora* (except for *A. yongei*) and the morphology of such species is largely unknown because little study has been performed on such Okinawan species (Curtis 2000, 2012).

The most common group of coral in Okinawa is the coral group *Acropora sensu stricto*, which is divided into many subclades of which the most abundant subclade is *A. gemmifera* (West & Southwood 1987), and other subclades of *Acropora* have not been identified for the entire Okinawa population (and the present study). The species belonging to this group are now reported to be important re-colonizers of degraded reefs of Okinawa, which suggests that the composition of coral assemblages in the future will largely be a reflection of the type of reef system present in a particular locality and of the capability of a species to restore the system.

We must keep these questions in mind when we perform coral reef restoration. We should not stop restoration of the coral reef, because it can be difficult to stop the further degradation of coral reefs in the future. The coral reefs around Okinawa are still recovering. We must understand the true meaning of coral reef recovery and we must work to help the coral reef to be well. We must ask how many coral reefs around Okinawa can restore. We should help the coral reef recovery and we should not stop restoration. The coral reef around Okinawa has already completed the recovery process. We cannot say that the coral reef around Okinawa is well. Restoration must be continued. It is necessary to be on guard for future problems. We must be prepared against the continued damage. While coral reef ecosystems are declining at alarming rates all over the world, coral reef restoration at

large is in its infancy. Placing too much emphasis on the success of a few projects is likely to discourage the many practitioners who have stopped their work. Small scale restoration projects that can make a difference in the future become actions of the present. The challenge of regenerating degraded or lost ecosystems is to apply the technologies of global and local landscape assessment to test the extent of ecosystem decline, and to use this information to demonstrate how to maximize and conserve the services that reefs provide to people (Mumby et al. 2006). Examples of models of how to determine reef state and restoration interventions are available and could be used in reconstructing reefs on degraded or even lost ecosystems, such as those of the Sesoko Island (Okinawa), the famous Great Barrier Reef , the Marianas Trench and St. Croix in the US Virgin Islands. Local fishermen and elders can demonstrate the importance of healthy reefs for the livelihood of local people and thus gain support and recognition. Then, efforts to restore the natural system can move towards a sustainable ecosystem. 5ec8ef588b
